Cross-channel anomalies without labelling customers as fraudsters

Hi,

This came up in a working session and nobody had the same definition.

A rapid move between transaction channels can indicate account takeover, customer recovery behaviour or an operational workaround.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: service failure explains most switches; security events drive channel switching; or newly opened accounts have a different normal pattern.

The discussion is currently being driven by anecdotes, and the teams involved are describing the same customers differently. This has returned because the previous answer was useful but not strong enough to become a standing rule. Use August 2020 as the new evidence point rather than recycling the earlier conclusion.

What we need to decide is which patterns belong in cyber monitoring and which belong in service monitoring. Please bring a model-ready table, data dictionary and an honest baseline, including a few cases we can trace from source to conclusion.

The available evidence is transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. No device identity or IP address is available; do not describe a new channel as a new device.

Thank you
