Why does the credit population differ across Risk and Finance?

Team,

Before this becomes another standing report, can we answer the real question?

Risk, Lending and Reporting are counting applications, approvals, booked loans and distressed accounts from different starting populations. The possible stories are that workflow timing explains most differences, that booked loans are missing from downstream repayment views, or that declined and withdrawn cases are mixed.

The operating teams agree that more journeys are failing; they disagree on whether the customer, the bank or a downstream party owns the failure.

Please prepare a model-ready table, data dictionary and an honest baseline. The output must help us decide the canonical population and exception rules for the next return.

Data available: the latest closed loan files available by the request date, including affordability, pricing and origination risk fields; collections cases, promises to pay and recovery payments; debit-order mandates, collection dates, suspensions and cancellations; transaction-level timestamps, channels, amounts, statuses and error context.

Please state the limitation plainly: Do not present this as an official regulatory return without the required regulatory taxonomy and sign-off.

Thanks
