Follow-up: when does channel switching become a security signal?

Hi team,

A rapid move between transaction channels can indicate account takeover, customer recovery behaviour or an operational workaround.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use April 2021 as the new evidence point rather than recycling the earlier conclusion. Several teams are reporting more failed or retried activity than they expected, but they do not agree on the cause. There are enough data exceptions to make a polished average dangerous; preserve the unresolved cases.

Can you test these explanations rather than choosing one at the start?
- security events drive channel switching
- service failure explains most switches
- newly opened accounts have a different normal pattern

The decision is which patterns belong in cyber monitoring and which belong in service monitoring. Please give us a model-ready table, data dictionary and an honest baseline.

You should be able to build the evidence from transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. No device identity or IP address is available; do not describe a new channel as a new device.

Thanks
