The account closes once; the bank may need to close it five times - 2025 control review

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

Internal Audit wants to test whether an account status change consistently stops transactions, ATM access, debit orders, collections and campaigns. There is no confirmed problem yet; this is a request to test an assumption before it becomes policy.

Could the answer be that manual exceptions are not documented consistently? Or are we actually seeing that controls propagate on the same day? I also do not want us to miss the possibility that some downstream systems lag.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use March 2025 as the new evidence point rather than recycling the earlier conclusion. The practical decision is whether this is an isolated exception, a design weakness or a control operating failure. Please send a control view with the exceptions, owner and reason each item was included; I need the exceptions and counter-examples, not only an average.

Work from monthly account snapshots, status events, limits, product enrolments and signatories; transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; debit-order mandates, collection dates, suspensions and cancellations; collections cases, promises to pay and recovery payments; campaign design and customer responses. The result is a data-based control test and still requires process-owner evidence.

Regards
