# A failed digital journey followed by cash access needs context

Morning,

I need help with something that sounds simple but probably is not.

A rapid move between transaction channels can indicate account takeover, customer recovery behaviour or an operational workaround. Please start with the decision we need to make, then show whether the available evidence is strong enough to support it.

The questions I would ask in the room are:
1. What would we expect to see if service failure explains most switches?
2. What evidence would instead support that newly opened accounts have a different normal pattern?
3. How do we rule out that security events drive channel switching?

We looked at a version of this before. For the November 2020 review, please show what changed and whether the earlier conclusion still holds. Please work towards which patterns belong in cyber monitoring and which belong in service monitoring. A useful output would be a control view with the exceptions, owner and reason each item was included.

Use transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. One caution: No device identity or IP address is available; do not describe a new channel as a new device.

Regards
