Which inflows disappear as quickly as they arrive? - 2024 control review

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

ALM wants a directional view of retail funding stability based on transaction behaviour and account persistence. Please start with the decision we need to make, then show whether the available evidence is strong enough to support it.

Could the answer be that salary-like and recurring inflows are more stable? Or are we actually seeing that large opening deposits overstate durable funding? I also do not want us to miss the possibility that customers with service problems move money out faster.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use September 2024 as the new evidence point rather than recycling the earlier conclusion. The practical decision is which behavioural assumptions deserve formal modelling when balance and regulatory data become available. Please send a working Excel file with the exception population and clear columns; I need the exceptions and counter-examples, not only an average.

Work from transaction-level timestamps, channels, amounts, statuses and error context; available initial-deposit records up to the request date; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. There are no daily account balances, wholesale funding positions or regulatory cash-flow buckets, so do not calculate LCR or NSFR.

Regards
