A funding-stability proxy from the data we actually have - 2023 control review

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

ALM wants a directional view of retail funding stability based on transaction behaviour and account persistence. Failure anecdotes are beginning to drive decisions, although retries and late posting may be making the problem look larger than the affected-customer population. There are enough data exceptions to make a polished average dangerous; preserve the unresolved cases.

Could the answer be that large opening deposits overstate durable funding? Or are we actually seeing that customers with service problems move money out faster? I also do not want us to miss the possibility that salary-like and recurring inflows are more stable.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use December 2023 as the new evidence point rather than recycling the earlier conclusion. The practical decision is which behavioural assumptions deserve formal modelling when balance and regulatory data become available. Please send a Power BI page with drill-through to a reproducible case list; I need the exceptions and counter-examples, not only an average.

Work from transaction-level timestamps, channels, amounts, statuses and error context; available initial-deposit records up to the request date; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. There are no daily account balances, wholesale funding positions or regulatory cash-flow buckets, so do not calculate LCR or NSFR.

Regards
