Which fraud alerts are actually operational noise?

Hi,

This came up in a working session and nobody had the same definition.

Investigators report that some suspicious patterns disappear once transaction timing, retries and customer contacts are reconstructed.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: a known service interaction explains the change; repeated attempts inflate velocity; or bank-side delay creates impossible sequences.

The discussion is currently being driven by anecdotes, and the teams involved are describing the same customers differently.

What we need to decide is which alert features should be corrected, retained or routed elsewhere. Please bring a working Excel file with the exception population and clear columns, including a few cases we can trace from source to conclusion.

The available evidence is transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; customer contacts, complaints and suggestions; monthly account snapshots, status events, limits, product enrolments and signatories. A plausible explanation is not automatic clearance; investigators still own the decision.

Thank you
