Are customer retries making incidents worse?

Hi,

This came up in a working session and nobody had the same definition.

During service degradation, repeated attempts can inflate volume and obscure the number of customers actually affected.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: customers retry the same action within minutes; channel switching follows a timeout; or automatic retry and human retry are being mixed.

There is no confirmed problem yet; this is a request to test an assumption before it becomes policy.

What we need to decide is how monitoring should count affected customers and when retry controls should activate. Please bring a short decision pack with no more than five slides and an attached evidence table, including a few cases we can trace from source to conclusion.

The available evidence is transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency. Without application session IDs, use account, amount, channel and time proximity as an explicit matching heuristic.

Thank you
