Why does the credit population differ across Risk and Finance?

Hi,

This came up in a working session and nobody had the same definition.

Risk, Lending and Reporting are counting applications, approvals, booked loans and distressed accounts from different starting populations.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: workflow timing explains most differences; booked loans are missing from downstream repayment views; or declined and withdrawn cases are mixed.

The discussion is currently being driven by anecdotes, and the teams involved are describing the same customers differently.

What we need to decide is the canonical population and exception rules for the next return. Please bring a control view with the exceptions, owner and reason each item was included, including a few cases we can trace from source to conclusion.

The available evidence is the latest closed loan files available by the request date, including affordability, pricing and origination risk fields; collections cases, promises to pay and recovery payments; debit-order mandates, collection dates, suspensions and cancellations; transaction-level timestamps, channels, amounts, statuses and error context. Do not present this as an official regulatory return without the required regulatory taxonomy and sign-off.

Thank you
