What is driving the non-rand flow?

Morning,

I need help with something that sounds simple but probably is not.

Treasury sees non-rand activity but needs to separate stable customer behaviour from isolated transactions and data artefacts. There is no confirmed problem yet; this is a request to test an assumption before it becomes policy.

The questions I would ask in the room are:

1. What would we expect to see if loan participations explain part of the flow?
2. What evidence would instead support that cross-border-enabled accounts are not the same as active cross-border users?
3. How do we rule out that a small group of customers drives most foreign-currency activity?

Please work towards whether to improve forecasting assumptions or investigate specific flow concentrations. A useful output would be a control view with the exceptions, owner and reason each item was included.

Use monthly account snapshots, status events, limits, product enrolments and signatories; transaction-level timestamps, channels, amounts, statuses and error context; loan participation and servicing records available by the request date. One caution: This data does not contain market positions, hedges or intraday liquidity; report customer-flow concentration only.

Regards
