When does channel switching become a security signal?

Hi,

This came up in a working session and nobody had the same definition.

A rapid move between transaction channels can indicate account takeover, customer recovery behaviour or an operational workaround.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: service failure explains most switches; security events drive channel switching; or newly opened accounts have a different normal pattern.

The operating teams agree that more journeys are failing; they disagree on whether the customer, the bank or a downstream party owns the failure. The first extracts did not reconcile, which means source precedence and exclusions must be part of the answer.

What we need to decide is which patterns belong in cyber monitoring and which belong in service monitoring. Please bring a model-ready table, data dictionary and an honest baseline, including a few cases we can trace from source to conclusion.

The available evidence is transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. No device identity or IP address is available; do not describe a new channel as a new device.

Thank you
