### Quick question: do origination PD bands separate later outcomes?

Morning,

I need help with something that sounds simple but probably is not.

Loan files contain origination PD, LGD and ECL fields, but the bank needs to know whether risk ordering survives into later repayment behaviour. Several teams are reporting more failed or retried activity than they expected, but they do not agree on the cause. Different teams have produced different answers from the same period, so population and timing rules need to be visible.

The questions I would ask in the room are:

1. What would we expect to see if higher PD bands show more arrears?
2. What evidence would instead support that product and vintage explain more than the score?
3. How do we rule out that missing or defaulted inputs create artificial separation?

Please work towards whether recalibration, segmentation or data remediation is the next step. A useful output would be a control view with the exceptions, owner and reason each item was included.

Use the latest closed loan files available by the request date, including affordability, pricing and origination risk fields; collections cases, promises to pay and recovery payments; transaction-level timestamps, channels, amounts, statuses and error context; debit-order mandates, collection dates, suspensions and cancellations. One caution: The data supports discrimination and outcome analysis, not a complete IFRS 9 validation without default definitions, macro scenarios and accounting policy.

Regards
