Are we collecting on the wrong day for the customer's cash flow?

Hi team,

Payments wants to test whether collection timing, rather than inability to pay, explains repeat debit-order failure.

The operating teams agree that more journeys are failing; they disagree on whether the customer, the bank or a downstream party owns the failure. There are enough data exceptions to make a polished average dangerous; preserve the unresolved cases.

Can you test these explanations rather than choosing one at the start?

- fixed collection rules work differently across customer groups
- retry timing improves success
- collection before regular inflow drives failure

The decision is whether to test alternative debit dates or change retry logic. Please give us a model-ready table, data dictionary and an honest baseline.

You should be able to build the evidence from debit-order mandates, collection dates, suspensions and cancellations; transaction-level timestamps, channels, amounts, statuses and error context; the latest closed loan files available by the request date, including affordability, pricing and origination risk fields; collections cases, promises to pay and recovery payments. Regular inflows are inferred from transaction patterns; no verified payroll calendar is available.

Thanks
