Reduce false positives without weakening controls

Hi team,

Investigators report that some suspicious patterns disappear once transaction timing, retries and customer contacts are reconstructed.

We looked at a version of this before. For the March 2020 review, please show what changed and whether the earlier conclusion still holds. Several teams are reporting more failed or retried activity than they expected, but they do not agree on the cause.

Can you test these explanations rather than choosing one at the start?

- a known service interaction explains the change
- repeated attempts inflate velocity
- bank-side delay creates impossible sequences

The decision is which alert features should be corrected, retained or routed elsewhere. Please give us a model-ready table, data dictionary and an honest baseline.

You should be able to build the evidence from transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; customer contacts, complaints and suggestions; monthly account snapshots, status events, limits, product enrolments and signatories. A plausible explanation is not automatic clearance; investigators still own the decision.

Thanks
