### Schema drift is becoming a reporting risk

---

Hi,

This came up in a working session and nobody had the same definition.

Data Engineering sees changing schemas and needs to distinguish safe expansion from business-definition drift.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: null patterns reveal a source rollout rather than missing customer data; renamed or recoded fields break history; or new fields are additive.

Several teams are reporting more failed or retried activity than they expected, but they do not agree on the cause. We looked at a version of this before. For the May 2020 review, please show what changed and whether the earlier conclusion still holds.

What we need to decide is the data contract, quarantine rule and backfill requirement. Please bring a Power BI page with drill-through to a reproducible case list, including a few cases we can trace from source to conclusion.

The available evidence is monthly account snapshots, status events, limits, product enrolments and signatories; monthly customer and KYC snapshots; transaction-level timestamps, channels, amounts, statuses and error context; the latest closed loan files available by the request date, including affordability, pricing and origination risk fields. A technical schema match does not prove semantic consistency; business owners must confirm meaning.

Thank you
