Dormancy may begin during onboarding

Morning,

I need help with something that sounds simple but probably is not.

Product wants to understand why some customers make an initial deposit but fail to establish recurring activity. There are enough data exceptions to make a polished average dangerous; preserve the unresolved cases.

The questions I would ask in the room are:

1. What would we expect to see if the account was opened for a one-off purpose?
2. What evidence would instead support that fees or a failed first journey discourage use?
3. How do we rule out that activation friction causes early dormancy?

We looked at a version of this before. For the September 2020 review, please show what changed and whether the earlier conclusion still holds. Please work towards which onboarding intervention or product proposition should be tested. A useful output would be a Power BI page with drill-through to a reproducible case list.

Use monthly account snapshots, status events, limits, product enrolments and signatories; available initial-deposit records up to the request date; transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; customer contacts, complaints and suggestions. One caution: The data cannot observe the customer's relationship with competing banks.

Regards
