Origination month may explain more than current arrears

Hi,

This came up in a working session and nobody had the same definition.

Portfolio risk is being discussed as a single book, although origination periods experienced different rates, channels and customer conditions.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: product mix creates the apparent vintage effect; operational debit failures contaminate credit outcomes; or recent vintages deteriorate faster.

The discussion is currently being driven by anecdotes, and the teams involved are describing the same customers differently. We looked at a version of this before. For the November 2020 review, please show what changed and whether the earlier conclusion still holds.

What we need to decide is which vintage needs deeper review and whether policy or operations owns the next action. Please bring a model-ready table, data dictionary and an honest baseline, including a few cases we can trace from source to conclusion.

The available evidence is the latest closed loan files available by the request date, including affordability, pricing and origination risk fields; collections cases, promises to pay and recovery payments; debit-order mandates, collection dates, suspensions and cancellations; transaction-level timestamps, channels, amounts, statuses and error context; time-appropriate news and macro-event context. Macro events provide context, not a causal estimate by themselves.

Thank you
