Debit day, salary timing and avoidable failure

Hi team,

Payments wants to test whether collection timing, rather than inability to pay, explains repeat debit-order failure.

We looked at a version of this before. For the January 2021 review, please show what changed and whether the earlier conclusion still holds. Failure anecdotes are beginning to drive decisions, although retries and late posting may be making the problem look larger than the affected-customer population. There are enough data exceptions to make a polished average dangerous; preserve the unresolved cases.

Can you test these explanations rather than choosing one at the start?

- fixed collection rules work differently across customer groups
- collection before regular inflow drives failure
- retry timing improves success

The decision is whether to test alternative debit dates or change retry logic. Please give us a short decision pack with no more than five slides and an attached evidence table.

You should be able to build the evidence from debit-order mandates, collection dates, suspensions and cancellations; transaction-level timestamps, channels, amounts, statuses and error context; the latest closed loan files available by the request date, including affordability, pricing and origination risk fields; collections cases, promises to pay and recovery payments. Regular inflows are inferred from transaction patterns; no verified payroll calendar is available.

Thanks
