Conversion is not the same as campaign impact

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

Analytics has been asked to report campaign success, but selected customers may already have been more likely to convert. Failure anecdotes are beginning to drive decisions, although retries and late posting may be making the problem look larger than the affected-customer population. Different teams have produced different answers from the same period, so population and timing rules need to be visible.

Could the answer be that the campaign creates incremental response? Or are we actually seeing that service problems suppress otherwise suitable offers? I also do not want us to miss the possibility that targeting explains the apparent lift.

We looked at a version of this before. For the April 2021 review, please show what changed and whether the earlier conclusion still holds. The practical decision is the treatment, control, success window and guardrail measures before the next campaign launches. Please send a one-page finding note plus the underlying CSV for our own review; I need the exceptions and counter-examples, not only an average.

Work from campaign design and customer responses; monthly account snapshots, status events, limits, product enrolments and signatories; transaction-level timestamps, channels, amounts, statuses and error context; customer contacts, complaints and suggestions. Historical campaign responses alone do not identify causal impact where no comparable control group exists.

Regards
