Cross-channel anomalies without labelling customers as fraudsters

Hi,

This came up in a working session and nobody had the same definition.

A rapid move between transaction channels can indicate account takeover, customer recovery behaviour or an operational workaround.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: security events drive channel switching; newly opened accounts have a different normal pattern; or service failure explains most switches.

The operating teams agree that more journeys are failing; they disagree on whether the customer, the bank or a downstream party owns the failure. This has returned because the previous answer was useful but not strong enough to become a standing rule. Use November 2021 as the new evidence point rather than recycling the earlier conclusion.

What we need to decide is which patterns belong in cyber monitoring and which belong in service monitoring. Please bring a control view with the exceptions, owner and reason each item was included, including a few cases we can trace from source to conclusion.

The available evidence is transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. No device identity or IP address is available; do not describe a new channel as a new device.

Thank you
