Quick question: A failed debit may be a calendar problem

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

Payments wants to test whether collection timing, rather than inability to pay, explains repeat debit-order failure. The operating teams agree that more journeys are failing; they disagree on whether the customer, the bank or a downstream party owns the failure.

Could the answer be that fixed collection rules work differently across customer groups? Or are we actually seeing that collection before regular inflow drives failure? I also do not want us to miss the possibility that retry timing improves success.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use January 2022 as the new evidence point rather than recycling the earlier conclusion. The practical decision is whether to test alternative debit dates or change retry logic. Please send a Power BI page with drill-through to a reproducible case list; I need the exceptions and counter-examples, not only an average.

Work from debit-order mandates, collection dates, suspensions and cancellations; transaction-level timestamps, channels, amounts, statuses and error context; the latest closed loan files available by the request date, including affordability, pricing and origination risk fields; collections cases, promises to pay and recovery payments. Regular inflows are inferred from transaction patterns; no verified payroll calendar is available.

Regards
