The account closes once; the bank may need to close it five times

Hi,

This came up in a working session and nobody had the same definition.

Internal Audit wants to test whether an account status change consistently stops transactions, ATM access, debit orders, collections and campaigns.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: controls propagate on the same day; some downstream systems lag; or manual exceptions are not documented consistently.

The operating teams agree that more journeys are failing; they disagree on whether the customer, the bank or a downstream party owns the failure. This has returned because the previous answer was useful but not strong enough to become a standing rule. Use March 2022 as the new evidence point rather than recycling the earlier conclusion.

What we need to decide is whether this is an isolated exception, a design weakness or a control operating failure. Please bring a model-ready table, data dictionary and an honest baseline, including a few cases we can trace from source to conclusion.

The available evidence is monthly account snapshots, status events, limits, product enrolments and signatories; transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; debit-order mandates, collection dates, suspensions and cancellations; collections cases, promises to pay and recovery payments; campaign design and customer responses. The result is a data-based control test and still requires process-owner evidence.

Thank you
