Follow-up: are customer retries making incidents worse?

Hi team,

During service degradation, repeated attempts can inflate volume and obscure the number of customers actually affected.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use March 2022 as the new evidence point rather than recycling the earlier conclusion. Failure anecdotes are beginning to drive decisions, although retries and late posting may be making the problem look larger than the affected-customer population.

Can you test these explanations rather than choosing one at the start?

- automatic retry and human retry are being mixed
- channel switching follows a timeout
- customers retry the same action within minutes

The decision is how monitoring should count affected customers and when retry controls should activate. Please give us a one-page finding note plus the underlying CSV for our own review.

You should be able to build the evidence from transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency. Without application session IDs, use account, amount, channel and time proximity as an explicit matching heuristic.

Thanks
