Follow-up: how stable are our retail inflows?

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

ALM wants a directional view of retail funding stability based on transaction behaviour and account persistence. The operating teams agree that more journeys are failing; they disagree on whether the customer, the bank or a downstream party owns the failure.

Could the answer be that large opening deposits overstate durable funding? Or are we actually seeing that salary-like and recurring inflows are more stable? I also do not want us to miss the possibility that customers with service problems move money out faster.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use June 2022 as the new evidence point rather than recycling the earlier conclusion. The practical decision is which behavioural assumptions deserve formal modelling when balance and regulatory data become available. Please send a control view with the exceptions, owner and reason each item was included; I need the exceptions and counter-examples, not only an average.

Work from transaction-level timestamps, channels, amounts, statuses and error context; available initial-deposit records up to the request date; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. There are no daily account balances, wholesale funding positions or regulatory cash-flow buckets, so do not calculate LCR or NSFR.

Regards
