Follow-up: which promises are realistic at the moment they are made?

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

Collectors record promises with different amounts and dates, and management needs a fair measure of promise quality. Failure anecdotes are beginning to drive decisions, although retries and late posting may be making the problem look larger than the affected-customer population.

Could the answer be that channel and timing affect outcomes? Or are we actually seeing that affordable promises are kept more often? I also do not want us to miss the possibility that partial payments are being treated inconsistently.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use February 2023 as the new evidence point rather than recycling the earlier conclusion. The practical decision is the promise definition, coaching view and model target. Please send a Power BI page with drill-through to a reproducible case list; I need the exceptions and counter-examples, not only an average.

Work from collections cases, promises to pay and recovery payments; transaction-level timestamps, channels, amounts, statuses and error context; the latest closed loan files available by the request date, including affordability, pricing and origination risk fields; customer contacts, complaints and suggestions. Do not rank individual collectors without workload, assignment and contact-attempt history.

Regards
