Follow-up: dormancy may begin during onboarding

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

Product wants to understand why some customers make an initial deposit but fail to establish recurring activity. Failure anecdotes are beginning to drive decisions, although retries and late posting may be making the problem look larger than the affected-customer population. Different teams have produced different answers from the same period, so population and timing rules need to be visible.

Could the answer be that activation friction causes early dormancy? Or are we actually seeing that the account was opened for a one-off purpose? I also do not want us to miss the possibility that fees or a failed first journey discourage use.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use December 2023 as the new evidence point rather than recycling the earlier conclusion. The practical decision is which onboarding intervention or product proposition should be tested. Please send a control view with the exceptions, owner and reason each item was included; I need the exceptions and counter-examples, not only an average.

Work from monthly account snapshots, status events, limits, product enrolments and signatories; available initial-deposit records up to the request date; transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; customer contacts, complaints and suggestions. The data cannot observe the customer's relationship with competing banks.

Regards
