Follow-up: A failed digital journey followed by cash access needs context

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

A rapid move between transaction channels can indicate account takeover, customer recovery behaviour or an operational workaround. The operating teams agree that more journeys are failing; they disagree on whether the customer, the bank or a downstream party owns the failure.

Could the answer be that newly opened accounts have a different normal pattern? Or are we actually seeing that security events drive channel switching? I also do not want us to miss the possibility that service failure explains most switches.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use February 2024 as the new evidence point rather than recycling the earlier conclusion. The practical decision is which patterns belong in cyber monitoring and which belong in service monitoring. Please send a working Excel file with the exception population and clear columns; I need the exceptions and counter-examples, not only an average.

Work from transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. No device identity or IP address is available; do not describe a new channel as a new device.

Regards
