Follow-up: the retry pattern needs to be separated from demand

Hi team,

During service degradation, repeated attempts can inflate volume and obscure the number of customers actually affected.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use March 2024 as the new evidence point rather than recycling the earlier conclusion. Several teams are reporting more failed or retried activity than they expected, but they do not agree on the cause. Different teams have produced different answers from the same period, so population and timing rules need to be visible.

Can you test these explanations rather than choosing one at the start?

- customers retry the same action within minutes
- automatic retry and human retry are being mixed
- channel switching follows a timeout

The decision is how monitoring should count affected customers and when retry controls should activate. Please give us a short decision pack with no more than five slides and an attached evidence table.

You should be able to build the evidence from transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency. Without application session IDs, use account, amount, channel and time proximity as an explicit matching heuristic.

Thanks
