Follow-up: rate sensitivity without pretending we have a full ALM model

Team,

Before this becomes another standing report, can we answer the real question?

The planning team needs to understand which product and customer groups are most exposed when lending and account rates change. The possible stories are that repayment stress is driven more by cash flow than by nominal rate, that fee-sensitive deposit activity changes after repricing, or that variable-rate borrowers show stress before fixed-rate borrowers.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use May 2024 as the new evidence point rather than recycling the earlier conclusion. There is no confirmed problem yet; this is a request to test an assumption before it becomes policy.

Please prepare a working Excel file with the exception population and clear columns. The output must help us decide where product repricing, customer communication or credit monitoring should be focused.

Data available: monthly account snapshots, status events, limits, product enrolments and signatories; the latest closed loan files available by the request date, including affordability, pricing and origination risk fields; transaction-level timestamps, channels, amounts, statuses and error context; collections cases, promises to pay and recovery payments; customer contacts, complaints and suggestions.

Please state the limitation plainly: This is a behavioural sensitivity study, not IRRBB, economic value of equity or a regulatory interest-rate calculation.

Thanks
