Follow-up: which inflows disappear as quickly as they arrive?

Morning,

I need help with something that sounds simple but probably is not.

ALM wants a directional view of retail funding stability based on transaction behaviour and account persistence. There is no confirmed problem yet; this is a request to test an assumption before it becomes policy.

The questions I would ask in the room are:

1. What would we expect to see if customers with service problems move money out faster?
2. What evidence would instead support that salary-like and recurring inflows are more stable?
3. How do we rule out that large opening deposits overstate durable funding?

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use June 2024 as the new evidence point rather than recycling the earlier conclusion. Please work towards which behavioural assumptions deserve formal modelling when balance and regulatory data become available. A useful output would be a model-ready table, data dictionary and an honest baseline.

Use transaction-level timestamps, channels, amounts, statuses and error context; available initial-deposit records up to the request date; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. One caution: There are no daily account balances, wholesale funding positions or regulatory cash-flow buckets, so do not calculate LCR or NSFR.

Regards
