Follow-up: the ATM pattern may be customer error or coordinated testing

Hi,

This came up in a working session and nobody had the same definition.

Cyber wants to know whether repeated PIN failures, balance enquiries and cash attempts form recognisable sequences before a card is blocked.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: normal forgotten-PIN behaviour dominates; a balance enquiry followed by rapid withdrawals marks higher risk; or specific terminals see repeated card testing.

Please start with the decision we need to make, then show whether the available evidence is strong enough to support it. This has returned because the previous answer was useful but not strong enough to become a standing rule. Use December 2024 as the new evidence point rather than recycling the earlier conclusion.

What we need to decide is which sequences should become monitoring rules and which would create unacceptable false positives. Please bring a short decision pack with no more than five slides and an attached evidence table, including a few cases we can trace from source to conclusion.

The available evidence is ATM attempts, host responses, PIN attempts, blocked-card state and latency; transaction-level timestamps, channels, amounts, statuses and error context; monthly account snapshots, status events, limits, product enrolments and signatories. There is no CCTV, device fingerprint or complete card-network feed, so classify behavioural patterns rather than confirmed attacks.

Thank you
