Follow-up: cross-channel anomalies without labelling customers as fraudsters

Team,

Before this becomes another standing report, can we answer the real question?

A rapid move between transaction channels can indicate account takeover, customer recovery behaviour or an operational workaround. The possible stories are that security events drive channel switching, that service failure explains most switches, or that newly opened accounts have a different normal pattern.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use February 2025 as the new evidence point rather than recycling the earlier conclusion. The discussion is currently being driven by anecdotes, and the teams involved are describing the same customers differently.

Please prepare a short decision pack with no more than five slides and an attached evidence table. The output must help us decide which patterns belong in cyber monitoring and which belong in service monitoring.

Data available: transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions.

Please state the limitation plainly: No device identity or IP address is available; do not describe a new channel as a new device.

Thanks
