A concentration map from the failures we can observe

Hi,

This came up in a working session and nobody had the same definition.

Vendor Risk needs a first-pass dependency map showing where the same external context appears across multiple customer journeys.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: apparent concentration is a source-label problem; one provider sits behind several channels; or the most frequent provider is not the most harmful.

The discussion is currently being driven by anecdotes, and the teams involved are describing the same customers differently. We looked at a version of this before. For the March 2025 review, please show what changed and whether the earlier conclusion still holds.

What we need to decide is which dependencies need proper inventory, resilience testing or exit planning. Please bring a control view with the exceptions, owner and reason each item was included, including a few cases we can trace from source to conclusion.

The available evidence is transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; SWIFT messages, correspondent alerts and nostro breaks. This is a behavioural dependency proxy, not a complete outsourcing register.

Thank you
