Which fraud alerts are actually operational noise? - 2025 control review

Hi team,

Investigators report that some suspicious patterns disappear once transaction timing, retries and customer contacts are reconstructed.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use September 2025 as the new evidence point rather than recycling the earlier conclusion. Please start with the decision we need to make, then show whether the available evidence is strong enough to support it.

Can you test these explanations rather than choosing one at the start?

- a known service interaction explains the change
- bank-side delay creates impossible sequences
- repeated attempts inflate velocity

The decision is which alert features should be corrected, retained or routed elsewhere. Please give us a Power BI page with drill-through to a reproducible case list.

You should be able to build the evidence from transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; customer contacts, complaints and suggestions; monthly account snapshots, status events, limits, product enrolments and signatories. A plausible explanation is not automatic clearance; investigators still own the decision.

Thanks
