When does channel switching become a security signal?

Hi,

This came up in a working session and nobody had the same definition.

A rapid move between transaction channels can indicate account takeover, customer recovery behaviour or an operational workaround.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: security events drive channel switching; newly opened accounts have a different normal pattern; or service failure explains most switches.

There is no confirmed problem yet; this is a request to test an assumption before it becomes policy.

What we need to decide is which patterns belong in cyber monitoring and which belong in service monitoring. Please bring a one-page finding note plus the underlying CSV for our own review, including a few cases we can trace from source to conclusion.

The available evidence is transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. No device identity or IP address is available; do not describe a new channel as a new device.

Thank you
