Payment retries need an outcome-level control

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

Payment attempts, reversals and late postings can create apparent duplicates or genuine duplicate customer impact. Failure anecdotes are beginning to drive decisions, although retries and late posting may be making the problem look larger than the affected-customer population. Different teams have produced different answers from the same period, so population and timing rules need to be visible.

Could the answer be that retries are correctly linked? Or are we actually seeing that late settlement creates false duplicates? I also do not want us to miss the possibility that some customers were debited more than once before reversal.

We looked at a version of this before. For the December 2019 review, please show what changed and whether the earlier conclusion still holds. The practical decision is the matching rule, customer-impact list and preventive control. Please send a control view with the exceptions, owner and reason each item was included; I need the exceptions and counter-examples, not only an average.

Work from transaction-level timestamps, channels, amounts, statuses and error context; debit-order mandates, collection dates, suspensions and cancellations; customer contacts, complaints and suggestions. Statement evidence is available only for selected accounts; use transaction identifiers and timing for the full population.

Regards
