Are we seeing pass-through accounts or ordinary cash-flow behaviour?

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

Financial Crime wants to test whether rapid receipt and onward movement forms a network pattern or reflects ordinary customer behaviour. Failure anecdotes are beginning to drive decisions, although retries and late posting may be making the problem look larger than the affected-customer population. The first extracts did not reconcile, which means source precedence and exclusions must be part of the answer.

Could the answer be that new accounts act as pass-through accounts? Or are we actually seeing that salary, family support or business cash flow explains the pattern? I also do not want us to miss the possibility that shared beneficiaries connect otherwise separate customers.

The practical decision is which cases deserve investigation and which monitoring rule needs a better peer group. Please send a model-ready table, data dictionary and an honest baseline; I need the exceptions and counter-examples, not only an average.

Work from transaction-level timestamps, channels, amounts, statuses and error context; monthly account snapshots, status events, limits, product enrolments and signatories; monthly customer and KYC snapshots; debit-order mandates, collection dates, suspensions and cancellations. The output is a triage hypothesis. Do not label a customer a mule without investigation and external evidence.

Regards
