A failed digital journey followed by cash access needs context

Morning,

I need help with something that sounds simple but probably is not.

A rapid move between transaction channels can indicate account takeover, customer recovery behaviour or an operational workaround. The operating teams agree that more journeys are failing; they disagree on whether the customer, the bank or a downstream party owns the failure. There are enough data exceptions to make a polished average dangerous; preserve the unresolved cases.

The questions I would ask in the room are:

1. What would we expect to see if service failure explains most switches?
2. What evidence would instead support that security events drive channel switching?
3. How do we rule out that newly opened accounts have a different normal pattern?

We looked at a version of this before. For the January 2020 review, please show what changed and whether the earlier conclusion still holds. Please work towards which patterns belong in cyber monitoring and which belong in service monitoring. A useful output would be a control view with the exceptions, owner and reason each item was included.

Use transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. One caution: No device identity or IP address is available; do not describe a new channel as a new device.

Regards
