Collections capacity is being spent on customers who self-cure

Morning,

I need help with something that sounds simple but probably is not.

Collections wants to reduce unnecessary contact by identifying customers who usually restore the account without intervention. Different teams have produced different answers from the same period, so population and timing rules need to be visible.

The questions I would ask in the room are:

1. What would we expect to see if balance recovery and payment timing identify self-cure?
2. What evidence would instead support that repeat NSF customers need a different treatment?
3. How do we rule out that past contact creates the apparent cure?

We looked at a version of this before. For the June 2020 review, please show what changed and whether the earlier conclusion still holds. Please work towards which accounts can receive a light-touch reminder and which need an agent. A useful output would be a one-page finding note plus the underlying CSV for our own review.

Use collections cases, promises to pay and recovery payments; transaction-level timestamps, channels, amounts, statuses and error context; customer contacts, complaints and suggestions; debit-order mandates, collection dates, suspensions and cancellations. One caution: Observed cure after contact is not proof that the contact caused it.

Regards
