Late posting, retries and unusual behaviour are being mixed

Morning,

I need help with something that sounds simple but probably is not.

Investigators report that some suspicious patterns disappear once transaction timing, retries and customer contacts are reconstructed. There is no confirmed problem yet; this is a request to test an assumption before it becomes policy.

The questions I would ask in the room are:

1. What would we expect to see if a known service interaction explains the change?
2. What evidence would instead support that repeated attempts inflate velocity?
3. How do we rule out that bank-side delay creates impossible sequences?

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use July 2020 as the new evidence point rather than recycling the earlier conclusion. Please work towards which alert features should be corrected, retained or routed elsewhere. A useful output would be a working Excel file with the exception population and clear columns.

Use transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; customer contacts, complaints and suggestions; monthly account snapshots, status events, limits, product enrolments and signatories. One caution: A plausible explanation is not automatic clearance; investigators still own the decision.

Regards
