The recovery sequence needs evidence

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

The resilience plan lists systems, but customers experience end-to-end services that cross ATM, card, transaction and communication processes. There is no confirmed problem yet; this is a request to test an assumption before it becomes policy.

Could the answer be that cash access degrades before account servicing? Or are we actually seeing that manual workarounds create later reconciliation breaks? I also do not want us to miss the possibility that recovery restores authorisation before posting catches up.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use November 2020 as the new evidence point rather than recycling the earlier conclusion. The practical decision is the order in which critical services should be recovered and tested. Please send a Power BI page with drill-through to a reproducible case list; I need the exceptions and counter-examples, not only an average.

Work from transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; customer contacts, complaints and suggestions; debit-order mandates, collection dates, suspensions and cancellations. Treat this as a historical service-impact rehearsal, not proof of infrastructure capacity.

Regards
