Quick question: the account closes once; the bank may need to close it five times

Hi,

This came up in a working session and nobody had the same definition.

Internal Audit wants to test whether an account status change consistently stops transactions, ATM access, debit orders, collections and campaigns.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: some downstream systems lag; manual exceptions are not documented consistently; or controls propagate on the same day.

The discussion is currently being driven by anecdotes, and the teams involved are describing the same customers differently. This has returned because the previous answer was useful but not strong enough to become a standing rule. Use December 2020 as the new evidence point rather than recycling the earlier conclusion.

What we need to decide is whether this is an isolated exception, a design weakness or a control operating failure. Please bring a Power BI page with drill-through to a reproducible case list, including a few cases we can trace from source to conclusion.

The available evidence is monthly account snapshots, status events, limits, product enrolments and signatories; transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; debit-order mandates, collection dates, suspensions and cancellations; collections cases, promises to pay and recovery payments; campaign design and customer responses. The result is a data-based control test and still requires process-owner evidence.

Thank you
