Quick question: security control or false-positive factory?

Team,

Before this becomes another standing report, can we answer the real question?

Card blocking protects customers, but repeated legitimate attempts and later complaints may reveal controls that are too blunt. The possible stories are that customers receive inconsistent recovery paths, that ordinary PIN errors create avoidable blocks, or that blocked cards follow genuinely unusual sequences.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use February 2021 as the new evidence point rather than recycling the earlier conclusion. The operating teams agree that more journeys are failing; they disagree on whether the customer, the bank or a downstream party owns the failure. There are enough data exceptions to make a polished average dangerous; preserve the unresolved cases.

Please prepare a short decision pack with no more than five slides and an attached evidence table. The output must help us decide where thresholds, escalation or customer communication should change.

Data available: ATM attempts, host responses, PIN attempts, blocked-card state and latency; transaction-level timestamps, channels, amounts, statuses and error context; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions.

Please state the limitation plainly: Do not label a block as incorrect without the rule decision and investigation outcome.

Thanks
