### Follow-up: A funding-stability proxy from the data we actually have

---

Hi,

This came up in a working session and nobody had the same definition.

ALM wants a directional view of retail funding stability based on transaction behaviour and account persistence.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: customers with service problems move money out faster; large opening deposits overstate durable funding; or salary-like and recurring inflows are more stable.

Several teams are reporting more failed or retried activity than they expected, but they do not agree on the cause. This has returned because the previous answer was useful but not strong enough to become a standing rule. Use September 2021 as the new evidence point rather than recycling the earlier conclusion.

What we need to decide is which behavioural assumptions deserve formal modelling when balance and regulatory data become available. Please bring a Power BI page with drill-through to a reproducible case list, including a few cases we can trace from source to conclusion.

The available evidence is transaction-level timestamps, channels, amounts, statuses and error context; available initial-deposit records up to the request date; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. There are no daily account balances, wholesale funding positions or regulatory cash-flow buckets, so do not calculate LCR or NSFR.

Thank you
