Follow-up: one failed payment may be generating five technical events

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

During service degradation, repeated attempts can inflate volume and obscure the number of customers actually affected. The operating teams agree that more journeys are failing; they disagree on whether the customer, the bank or a downstream party owns the failure.

Could the answer be that channel switching follows a timeout? Or are we actually seeing that automatic retry and human retry are being mixed? I also do not want us to miss the possibility that customers retry the same action within minutes.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use November 2021 as the new evidence point rather than recycling the earlier conclusion. The practical decision is how monitoring should count affected customers and when retry controls should activate. Please send a Power BI page with drill-through to a reproducible case list; I need the exceptions and counter-examples, not only an average.

Work from transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency. Without application session IDs, use account, amount, channel and time proximity as an explicit matching heuristic.

Regards
