Follow-up: card replacement may be solving one problem and creating another

Hi all,

I may be joining dots that do not belong together, so please challenge the premise.

Card Operations needs to know whether replacement cards become usable quickly and whether old-card attempts continue after reissue. Failure anecdotes are beginning to drive decisions, although retries and late posting may be making the problem look larger than the affected-customer population. The first extracts did not reconcile, which means source precedence and exclusions must be part of the answer.

Could the answer be that ATM and transaction channels reflect card history differently? Or are we actually seeing that customers resume normal use quickly? I also do not want us to miss the possibility that old credentials continue to generate declines.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use December 2021 as the new evidence point rather than recycling the earlier conclusion. The practical decision is which reissue controls or customer messages need improvement. Please send a model-ready table, data dictionary and an honest baseline; I need the exceptions and counter-examples, not only an average.

Work from monthly account snapshots, status events, limits, product enrolments and signatories; ATM attempts, host responses, PIN attempts, blocked-card state and latency; transaction-level timestamps, channels, amounts, statuses and error context; customer contacts, complaints and suggestions. Card numbers are historical lists in the account snapshot; use issue and expiry dates to determine the active card.

Regards
