Who self-cures, and who is harmed by unnecessary contact?

Team,

Before this becomes another standing report, can we answer the real question?

Collections wants a prioritisation model, but validation must separate default risk from the effect of different contact strategies. The possible stories are that contact channel changes promise-kept rates, that high-risk customers need tailored arrangements rather than more attempts, or that some customers self-cure without intervention.

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use February 2022 as the new evidence point rather than recycling the earlier conclusion. The operating teams agree that more journeys are failing; they disagree on whether the customer, the bank or a downstream party owns the failure. There are enough data exceptions to make a polished average dangerous; preserve the unresolved cases.

Please prepare a working Excel file with the exception population and clear columns. The output must help us decide whether a model can support treatment allocation and what experiment is needed next.

Data available: collections cases, promises to pay and recovery payments; customer contacts, complaints and suggestions; transaction-level timestamps, channels, amounts, statuses and error context; the latest closed loan files available by the request date, including affordability, pricing and origination risk fields.

Please state the limitation plainly: Observational data cannot prove treatment causality; recommend a controlled test where appropriate.

Thanks
