Follow-up: collections capacity is being spent on customers who self-cure

Hi,

This came up in a working session and nobody had the same definition.

Collections wants to reduce unnecessary contact by identifying customers who usually restore the account without intervention.

I do not want a dashboard that simply counts the outcome. Start with the competing explanations: past contact creates the apparent cure; balance recovery and payment timing identify self-cure; or repeat NSF customers need a different treatment.

Several teams are reporting more failed or retried activity than they expected, but they do not agree on the cause. This has returned because the previous answer was useful but not strong enough to become a standing rule. Use June 2022 as the new evidence point rather than recycling the earlier conclusion.

What we need to decide is which accounts can receive a light-touch reminder and which need an agent. Please bring a Power BI page with drill-through to a reproducible case list, including a few cases we can trace from source to conclusion.

The available evidence is collections cases, promises to pay and recovery payments; transaction-level timestamps, channels, amounts, statuses and error context; customer contacts, complaints and suggestions; debit-order mandates, collection dates, suspensions and cancellations. Observed cure after contact is not proof that the contact caused it.

Thank you
