Follow-up: cross-channel anomalies without labelling customers as fraudsters

Morning,

I need help with something that sounds simple but probably is not.

A rapid move between transaction channels can indicate account takeover, customer recovery behaviour or an operational workaround. Several teams are reporting more failed or retried activity than they expected, but they do not agree on the cause.

The questions I would ask in the room are:

1. What would we expect to see if security events drive channel switching?
2. What evidence would instead support that newly opened accounts have a different normal pattern?
3. How do we rule out that service failure explains most switches?

This has returned because the previous answer was useful but not strong enough to become a standing rule. Use August 2022 as the new evidence point rather than recycling the earlier conclusion. Please work towards which patterns belong in cyber monitoring and which belong in service monitoring. A useful output would be a short decision pack with no more than five slides and an attached evidence table.

Use transaction-level timestamps, channels, amounts, statuses and error context; ATM attempts, host responses, PIN attempts, blocked-card state and latency; monthly account snapshots, status events, limits, product enrolments and signatories; customer contacts, complaints and suggestions. One caution: No device identity or IP address is available; do not describe a new channel as a new device.

Regards
